

Clear the Website Cache Safely

Version: v1.1 | Required access: Editor for an available record/page cache action; Administrator or Blue Nova for approved sitewide/server cache controls

When cache clearing applies

- WordPress confirmed that the correct content was saved.
- The exact public page still shows older information.
- You know the exact public URL visitors use. Cache clearing does not save work and does not correct wrong content.

Use the smallest safe sequence

- Review the approved change and select **Save**, **Update**, or **Publish** once.
- Wait for WordPress to confirm the save.
- Keep the exact public URL. Do not add a question mark or test text.
- If available, use the changed row's **Clear Cache** action.
- Open the exact public URL and hard refresh once:
- Windows: **Ctrl + F5**
- Mac: **Command + Shift + R**
- If the regular browser remains stale, check the same URL in a private or Incognito window.
- Use an approved **Breeze Purge All Cache** only when the change affects shared pages and the smaller clear was insufficient.
- Use a Varnish purge only when specifically authorized. Otherwise contact Blue Nova.

Never do these without Blue Nova direction

- Repeatedly click Update, Publish, or cache purge controls.
- Change Breeze, Cloudways, Varnish, Redis, object-cache, CDN, database, image, plugin, or optimization settings.
- Restart services, disable Varnish, install plugins, or purge unrelated content.

Verify publicly

- Open the exact canonical public URL.
- Confirm the visible change and test affected links at desktop size.
- Repeat at phone size and check for unreadable text, broken controls, or horizontal overflow.

Always finish with: Save > clear the applicable cache > open the exact public URL > verify the visible result on desktop and phone. If it is still wrong or missing, stop and contact Blue Nova.
